

Presentation: The Ambient Swarm

Target Time: 3 Minutes **Audience:** AI Founders, Tinkerers, Engineers **Vibe:** Confident, fast-paced, highly technical but grounded in a magical UX.

Part 1: The Pitch (1.5 Minutes)

(Slide 1: Title Slide - A blank screen with a single iMessage chat bubble: "Agents belong where we already live.")

Speaker 1: "Every AI agent we build today suffers from the same fatal flaw: to use it, the user has to stop what they are doing, open a new tab, download a new app, or log into a new dashboard. We are forcing users to come to the AI.

Today, we are bringing the AI to the user. We built an agent that lives entirely inside your phone's native contacts."

(Slide 2: A screenshot of a standard iOS group chat with 3 people, one of them is "AI Agent")

Speaker 1: "Meet our project. It's an ambient, multi-tenant AI swarm that you just add to your standard SMS or MMS group chats.

It requires zero installation, no app downloads, and no passwords. You just add the phone number to a group text with your friends or co-workers, and it sits there silently. It costs zero compute—until you @mention it."

(Slide 3: Architecture Diagram - highlighting Zero-Trust and Cortex)

Speaker 1: "Now, as engineers, you know the nightmare of putting an LLM in a group chat. Whose context does it use? How do you secure it? If I tell it to pull a GitHub repo, whose token is it using?

We solved this using a **Zero-Trust, Event-Sourced Orchestration Swarm**.

When you text the agent, Twilio passes your phone number to our FastAPI gateway. That phone number is your primary key. Our Orchestrator AI has **no tool access**. None. To prevent prompt injection and blast radius, it delegates tasks to ephemeral, isolated sub-agents.

It spins up a Context Agent linked to your personal semantic memory in Cortex, and an Execution Agent mounted with *your* specific MCP tools. It does the work, drops the answer in the chat, and then a background sub-agent asynchronously updates your long-term memory."

(Slide 4: Live Demo - Transition to mirrored phone screens on the projector)

Speaker 1: "That's the theory. Let's look at the reality. My co-founder and I are in a standard group chat right now."

Part 2: The Live Demo Choreography (1 Minute)

(On screen: Two phones mirrored side-by-side, or one phone clearly showing a group text.)

Speaker 2: "We're arguing over a hackathon project, and I need the AI to check my code. Watch this."

Action: Speaker 2 texts the group chat:

"@agent, look up my notes on the auth bug and check the latest commit on my backend repo to see if I fixed it."

Speaker 2: "Now, the agent knows my phone number, but I haven't given it access to my

GitHub yet. I don't need to go find a portal. The agent brings the friction to me."

Action: The Agent instantly replies to the group chat:

"I need your permission to access GitHub to check that repo. Secure your workspace and connect tools here: [Link]"

Speaker 2: "I click the link. It uses Twilio Verify to send me a silent OTP—my phone number *is* my account. I click 'Connect GitHub'."

Action: Speaker 2 taps the link, taps a single "Connect" button on a sleek web UI, and flips back to the iMessage thread.

Speaker 2: "The token is now injected into my Cortex memory graph. Without me having to re-prompt it, the orchestrator recognizes the state change, spins up the GitHub MCP sub-agent, and synthesizes the answer."

Action: The Agent texts back into the group chat:

"I checked Cortex. Your backend repo is 'sms-swarm-core'. I pulled the latest commit via GitHub. You did fix the auth bug, but you left a console.log exposing the Twilio token in line 42. You might want to patch that."

Speaker 1: "And because it's multi-tenant, if my co-founder @mentions it right now to check *his* calendar, the swarm dynamically mounts *his* tools, completely isolating our environments within the exact same group chat."

Part 3: The Finale (30 Seconds)

(Slide 5: A massive QR Code and a Phone Number on the left. On the right, a live, dark-mode terminal showing real-time event logs.)

Speaker 1: "We didn't just build a mock API wrapper this weekend. We built a scalable, multi-tenant enterprise gateway.

To prove it, take out your phones right now. Scan that QR code or text that number. Drop it into a group text with the person sitting next to you, or just text it directly and say hello.

Because you aren't in our system yet, it will dynamically generate a Just-In-Time onboarding flow for every single one of you.

The dashboard on the right is our live telemetry. Go ahead and wake up the swarm."

(Leave the slide up as the terminal immediately starts lighting up with incoming webhook events, JIT auth dispatches, and sub-agent spins from the audience.)
